

# Hour-scale slow changes in songs might reflect motivation and arousal in songbirds

T. KOUMURA & K. OKANOYA  
(The Univ. of Tokyo)

**Conclusions** Classified notes in the songs with as little human intervention as possible. → Worked well. Characterized hour-scale change in the note sequence pattern. → Found periodic patterns.

## Bird song

Complex temporal & spectral structure.  
Multiple elements (notes) in a sequence.

## Song Recording

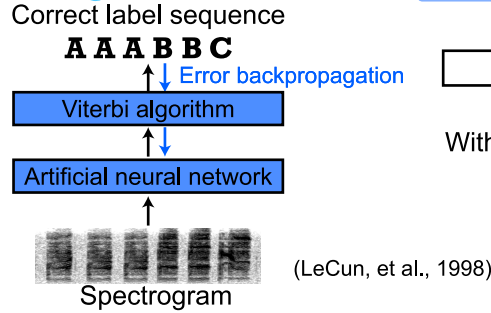

3 birds  
20523±5992 notes  
44.6±6.9 minutes in a day

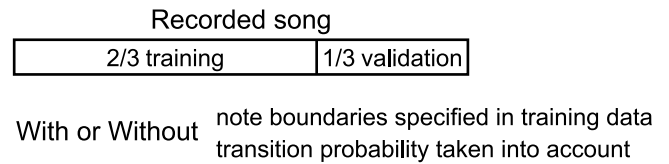

## Goal

## Training

## Evaluation

## Typical result

## Validation score

$$\text{Error ratio} = \frac{\text{Levenshtein distance between correct \& output sequences}}{\text{Length of correct sequence}}$$

		Transition scores	
		+	-
Note positions	+	0.21±0.14%	0.28±0.19%
	-	0.33±0.15%	0.36±0.11%

(Ave.±std over 3 birds)

Better with transition scores  
note boundaries

## Motif-to-motif transition probabilities

Motif: frequently appearing sequence pattern

Branch points in motif sequences

Determination of the most suitable window width to best predict the observed data

## Transition probabilities
